## ABSTRACT

An investigation was conducted in the old Himalayan piedmont plain soils in farmers field at Kanta, Dinajpur during 1992-93 and 1993-94 cropping seasons to asses effects of nutrient management in sugarcane (var. Isd 19) intercropped with potato (var. cardinal). Zn showed beneficial effects on yield of cane. Yield response of cane were more pronounced with Ca and Mg fertilization. Combined effect of NPKS Zn Ca and Mg significantly increased the potato yield and improved the growth parameters of sugarcane and finally obtained 67.2 kg additional sugarcane yield by addition of each kg of nutrients. Maximum net benefit of Tk. 96,132/ha and the highest marginal rate of return (MRR) of 180% was found owing to the use of these elements compared to sole cane. Application of  $N_{150} (P_2O_5)_{120} (K_2O)_{180} S_{10} Zn_8 Ca_{20} Mg_{20}$  to sugarcane with  $N_{150} (P_2O_5)_{60} (K_2O)_{130} S_{20} Zn_4 Mg_{10} kg ha^{-1}$  to potato respectively was found to be sufficient for sugarcane-potato intercropped situation in old Himalayan piedmont plain soils of Bangladesh.

## INTRODUCTION

Substantial advantage in yield from intercropping compared with sole cropping accrues from complementary effects of different crops on each other making better use of resource when grown together (Willey, 1979). Sugarcane is a long duration crop which requires 12-14 months from planting to harvesting. Some cane growers cannot afford to keep their land engaged for such a long period for sugarcane. Intercropping of different winter crops especially potato with sugarcane has a number of advantages. Potato intercropping not only gives an additional income but also increase yield of sugarcane through the complementary effects. Yield stability due to intercropping of potato has been reported else where (Okigbo, 1974; Rao and Shetty, 1976). In Bangladesh potato occupies 15% of total area intercropped with sugarcane (Imam *et al.* 1990). The combined return of cane and potato was always higher when both the crops were planted together and received their full rates of fertilizer (Imam *et al.* 1990). Systematic information is needed on the effects of nutrient management of potato with sugarcane. Hence, an experiment was conducted to find out the most economically acceptable nutrient levels for potato intercropping with sugarcane in the Old Himalayan Piedmont plain soils of Bangladesh.

## MATERIALS AND METHODS

The field experiment was conducted at farmers field in Gangachara series soils of Dinajpur district in Bangladesh during the cropping seasons 1992-93 and 1993-94 on a sandy loam soils. Initial soil samples were collected and prepared systematically for laboratory analysis. The pH was determined by glass electrode pH meter. Analysis is made for  $NH_4^4-N$ , Active acidity, Ca and Mg using IN KCl extraction procedure. The sample is analysed for P, K, Cu, Fe, Mn and Zn using the modified sodium bicarbonate

extraction procedure. Analysis is made for S and B using the  $\text{Ca H}_4 (\text{PO}_4)_2$  extraction procedure (Hunter, 1980). Nutrient status of the initial soil is shown in the Table 1. The critical level of each element has also been shown in the table 1.

**Table 1. Nutrient status of soils under study.**

| Location       | pH  | OM%  | AA  | Ca  | Mg<br>meq% | K    | NH <sub>4</sub> -N | P  | Mn  | S<br>(ppm) | B   | Cu  | Fe  | Zn  |
|----------------|-----|------|-----|-----|------------|------|--------------------|----|-----|------------|-----|-----|-----|-----|
| Dinajpur       | 5.3 | 1.25 | 0.8 | 0.9 | 0.16       | 0.08 | 14                 | 35 | 4.2 | 37         | 1.6 | 2.6 | 139 | 0.9 |
| Critical level | -   | -    | -   | 2   | 0.8        | 0.2  | 75                 | 20 | 5.0 | 14         | 0.2 | 1.0 | 20  | 2   |

The experiment was laid down in RCB design with three replications. Individual plot size was 80 sq.m (8m x 10m). A package of N P K S Zn Ca and Mg with variable rates were practiced. For field experiment, before selecting treatment combinations soils of experimental sites were analysed for fixation studies of different nutrients and after that green house studies were also made for missing element trial. The treatments combination were as follows:

| Treatment      | For sugarcane (kg/ha) |                        |                      |    |    |    |    |      | For potato (kg/ha) |                        |                      |    |    |    |      |
|----------------|-----------------------|------------------------|----------------------|----|----|----|----|------|--------------------|------------------------|----------------------|----|----|----|------|

\*CD means cowdung.

After the final land preparation, 30 d old soil bed settlings (var. Isd 19) were transplanted in late December at 1.0m between row spacing. Simultaneously the potato (Var. cardinal) were planted in rows between the vacant space of two rows of sugarcane in November. Each crop in each treatments received fertilizers as shown in above table. After land preparation full dose of  $\text{P}_2\text{O}_5$  (as TSP), S (as gypsum), Zn (as zinc sulphate), Mg (as magnesium oxide), Ca (as calcium oxide), Cowdung (CD) and half of  $\text{K}_2\text{O}$  (as MP) were applied in the trenches for cane as basal dose. One third of N (as urea) was applied as top dressing after 20 d of transplanting. Rest of N and  $\text{K}_2\text{O}$  were applied in two equal installments within 100 d and 150 d after cane plantation.

For intercrop potato, half of the total N and full dose of  $\text{P}_2\text{O}_5$ ,  $\text{K}_2\text{O}$ , S, Mg, Zn and cowdung were applied between the vacant space of two cane rows. Remaining N was applied after 30-40 d of potato plantation. The recommended crop management practices were adopted for cane as well as intercrop (Potato).

## RESULTS AND DISCUSSION

### Laboratory studies

The analytical results of initial soil of the experimental plot indicates (Table 1) that the soils of Gangachara series was deficient in N, Zn, Ca, Mg and exchangeable K. Available P, S, B, Cu and Fe of the soils were above critical level. Mn content was very close to optimum level in the soils.

### Yield and yield attributes of cane

Significant differences in tiller, number of millable cane and yield were obtained in different treatments in sugarcane + Potato intercropping pattern in both the years (Table 2). Pooled data for 2 years indicated that the highest number of effective tiller ( $161.2 \times 10^3 \text{ ha}^{-1}$ ), millable cane ( $110.8 \times 10^3 \text{ ha}^{-1}$ ) and cane yield ( $85.2 \text{ t ha}^{-1}$ ) was produced by cane + potato with the treatment  $T_4$ . Similar results were found by Rath and Singh (1979) and Agarwal (1973) who reported that crops like potato, radish and spinach have exert positive influence on the production of number of millable cane and yield. Marked significant response of yield and yield attributes of cane in both the years are observed with the treatment  $T_4$  when Zn, Mg and Ca were added with NPKS. Zinc application increased yield of cane by 8% over the treatment  $T_3$  where Zn was not used. Rahman *et al.* (1992) also obtained the individual application of Zn @  $8 \text{ Kg ha}^{-1}$  increased 8.7% cane yield compared to control. Addition of Mg and Ca increased yield of cane by about 31% over treatment  $T_2$  where Ca & Mg are not applied. All the treatment showed marked improvement of both the cane and tuber yield over control. It is assumed that sugarcane is likely to be benefited from combined effect of Zn, Mg and Ca with higher rates of NPKS nutrient application. Nutrient applied to potato and management practices ultimately induced greater yield of cane. On the other hand, treatment  $T_4$ , where all types of nutrient was applied both in cane and potato produced 13.3% higher cane yield than that of purestand cane. Higher yield of cane under such combination was also reported by Rath and Singh (1980). There were significant differences in the recoverable sucrose percentage under different treatments in the first year where the highest recovery was found with  $T_4$ . However, it appeared insignificant in the second year. It may be clear that potato intercropped with sugarcane did not have any adverse effects on growth and yield of cane, rather it produced synergistic effects on cane yield. It is also assumed that sugarcane being a long duration nature which capitalized on the residual resources left by potato. The results agreed with the findings of Verma and Yadav (1988).

### Potato yield

Gradual improvement of yield was conspicuous with the addition of different nutrient elements (Table 2). The mean of two years yield record showed the highest production with  $T_5$  where organic matter was added along with chemical fertilizers and the results were statistically significant. Such yield improvement may be attributed due to the use of organic matter. Improvement of potato yield due to application of organic matter was also noticed by Singh and Singh (1978).

### Nutrient use efficiency

While considering the nutrient use efficiency in sugarcane-potato intercrop combination, it is revealed from the yield data that  $T_4$  out yielded the other treatments. In this treatment around 67.2 kg sugarcane yield was obtained by addition of each kg of nutrients. Gradual yield improvement was noticed with the increase of rate of nutrients and addition of new elements which reached the maximum at  $T_4$  and started to decline beyond that (Figure 1). The highest adjusted yield of cane (potato yield converted into

cane yield on the basis of market price) was also received in the same treatment. This indicated the better utilization of nutrient applied to cane and accrued through the utilization of residual nutrient left after harvest of potato. Such yield advantage and better utilization of nutrient in intercropped (Mixed cropped) was also reported by Willey (1979) and Hossain (1984). According to them the intercrops may draw nutrient from larger volume of soil than single crop stand because of some degrees of mutual avoidance of root systems and perhaps more root soil contact in the same volume of soil.

**Table 3b. Marginal analysis of the undominated fertilizer response data.**

| Net benefit (Tk. ha <sup>-1</sup> ) | Treatment      | Variable cost (Tk. ha <sup>-1</sup> ) | Change from the next highest benefit |                                    |                               |
|-------------------------------------|----------------|---------------------------------------|--------------------------------------|------------------------------------|-------------------------------|
|                                     |                |                                       | Marginal increase in net benefit     | Marginal increase in variable cost | Marginal rate of return (MRR) |
| 96,132                              | T <sub>4</sub> | 23,408                                | 4,787                                | 2640                               | 1.8                           |
| 91,345                              | T <sub>3</sub> | 17,768                                | 17,768                               | 6538                               | 1.5                           |
| 81,329                              | T <sub>2</sub> | 11,230                                | 18,425                               | 11,230                             | 1.6                           |
| 62,372                              | T <sub>1</sub> | -                                     | -                                    | -                                  | -                             |

Price of fertilizer (Tk. Kg<sup>-1</sup>) Urea, 5.50; TSP, 9.00; MP, 7.00; Gypsum, 3.50; Zinc, 30.00; CaO, 60.00; MgO, 100.00; Cowdung 0.50. Price of sugarcane Tk. 1004.00 per ton; Potato Tk. 5000.00 per ton.

Maximum net benefit (for two crops) of Tk. 96,132/- ha<sup>-1</sup> was obtained in T<sub>4</sub> which was followed by Tk. 91,345/- ha<sup>-1</sup> in T<sub>3</sub>. The marginal analysis of the undominated response data (Table 3b) indicated that the highest marginal rate of return (MRR) of 180% was obtained in T<sub>4</sub> followed by 150% in T<sub>3</sub> and 160% in T<sub>2</sub>. Therefore, it is suggested that treatment T<sub>4</sub> is the economically acceptable treatment in this soil condition.

### ACKNOWLEDGEMENTS

The authors are thankful to BARC and CIDA for providing necessary fund for carrying out this investigation.
